Abstract.—Construction of dams in North America has affected changes in the early life history, growth, and condition of anadromous salmonids. Prior to dam construction, the freshwater life cycle of Snake River fall chinook salmon *Oncorhynchus tshawytscha* was complete by early July about 3 months after fry emergence. Dam construction in the 1950's, 1960's, and 1970's blocked passage to the historic production area of Snake River

the water temperature regimes of these areas, and impounded the downstream migration route of smolts. Young fall chinook salmon in the three main present-day production areas can reside in freshwater until late fall, and some fish hold over in reservoirs until the following spring. Condition and growth are relatively high for parr and smolts of all three present-day production areas. Rearing during periods of decreasing day length and slightly slower growth helps explain why some fall chinook salmon

Date

Figure 1.— Sideways box plots showing the timing of fry presence (Top), timing of parr presence (Middle), mean daily water temperature and day length (Bottom) in 1995 for the upper and lower reaches of the Snake River (abbreviated upper Snake and lower Snake) and the lower Clearwater River (abbreviated lower Clrwtr). The vertical sides of each box are the 25th and 75th percentiles, the vertical line within each box is the median, the horizontal dotted lines extend to the upper and lower fences (e.g., 25th percentile minus 1.5 multiplied by the interquartile range), and the asterisks are outliers (i.e., greater than upper fence or less than lower fence). Different letters in a box indicate that the date distribution differed significantly (alpha = 0.05). Water temperature data were collected by the Idaho Power Company, Boise, Idaho, U. S. Fish and Wildlife Service, Ahsahka, Idaho, and the U. S. Geological Survey. Photoperiod data were collected by the U. S. Navy.
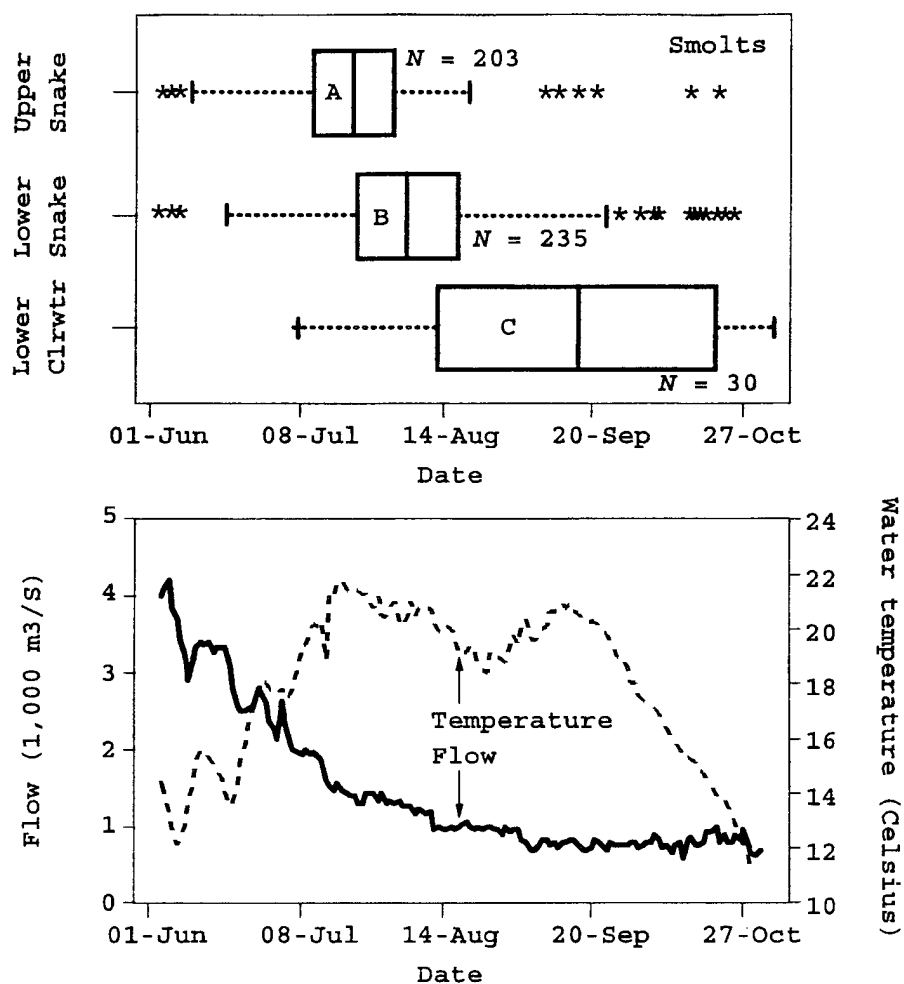

Figure 2.—Sideways box plots showing passage timing at Lower
Granite Dam for PIT-tagged smolts from the upper and lower
reaches of the Snake River (abbreviated upper Snake and lower
Snake) and the lower Clearwater River (abbreviated lower
Clrwtr)(Top), and the mean daily water flow and temperature
(Bottom) measured in Lower Granite Reservoir by the U. S. Army
Corps of Engineers in 1995. The vertical sides of each box are
the 25th and 75th percentiles, the vertical line within each box
is the median, the horizontal dotted lines extend to the upper
and lower fences (e.g., 25th percentile minus 1.5 multiplied by
the interquartile range), and the asterisks are outliers (i.e.,
greater than upper fence or less than lower fence). Different
letters in a box indicate that the date distribution differed
significantly (alpha = 0.05).

Table 1.— Mean condition factors (*K*) and absolute growth rates for wild subyearling chinook salmon parr that were collected in the upper and lower reaches of the Snake and lower Clearwater River in a beach seine, and for smolts that were recaptured at Lower Granite Dam or Little Goose Dam, 1992–2000.
